

Ecological site F018XI204CA North-facing Steep Draws and Hillslopes

Last updated: 4/24/2024 Accessed: 05/20/2024

General information

Provisional. A provisional ecological site description has undergone quality control and quality assurance review. It contains a working state and transition model and enough information to identify the ecological site.

MLRA notes

Major Land Resource Area (MLRA): 018X-Sierra Nevada Foothills

Major Land Resource Area (MLRA) 18, Sierra Nevada Foothills is located entirely in California and runs north to south adjacent to and down-slope of the west side of the Sierra Nevada Mountains (MLRA 22A). MLRA 18 includes rolling to steep dissected hills and low mountains, with several very steep river valleys. Climate is distinctively Mediterranean (xeric soil moisture regime) with hot, dry summers, and relatively cool, wet winters. Most of the precipitation comes as rain; average annual precipitation ranges from 15 to 55 inches in most of the area (precipitation generally increases with elevation and from south to north). Soil temperature regime is thermic; mean annual air temperature generally ranges between 52 and 64 degrees F. Geology is rather complex in this region; there were several volcanic flow and ashfall events, as well as tectonic uplift, during the past 25 million years that contributed to the current landscape.

LRU notes

This LRU (designated XI) is located on moderate to steep hills in the Sierra Nevada Foothills east of Sacramento, Stockton and Modesto, CA. Various geologies occur in this region: metavolcanics, granodiorite, slate, marble, argillite, schist and quartzite, as well as ultramafic bands to a limited and localized extent. It includes mesa formations from volcanic flows, where vernal pool habitats occur. Soil temperature regime is thermic and soil moisture regime is xeric. Elevation ranges between 300 and 3400 feet above sea level. Precipitation ranges from 14 to 42 inches annually. Most precipitation falls between the months of November and March in the form of rain. Dominant vegetation includes annual grasslands, blue oak (Quercus douglasii), interior live oak (Quercus wislizeni), chamise (Adenostoma fasciculatum), buckbrush (Ceanothus cuneatus), and foothill pine (Pinus sabiniana).

Classification relationships

CLASSIFICATION RELATIONSHIPS

This site is located within M261F, the Sierra Nevada Foothills Section, (McNab et al., 2007) of the National Hierarchical Framework of Ecological Units (Cleland et al., 1997), M261Fb, the Lower Foothills Metamorphic Belt Subsection.

Level III and Level IV ecoregions systems (Omernik, 1987, and EPA, 2011) are: Level III, Central California Foothills and Coastal Mountains and Level IV, Ecoregion 6b, Northern Sierran Foothills, Ecoregion 6c, Comanche Terraces.

Ecological site concept

This site is found on steep hills on north-facing aspects on backslopes and footslopes, often in cooler drainages where soil temperatures border mesic. Parent material is generally of metasedimentary or granitic origin. Slopes typically range from 25 to 60%. Mean annual precipitation typically ranges from 32 to 38 inches, and elevation ranges from 1250 to 2000 feet.

Slope aspect is the overriding abiotic factor defining this ecological site, and tends to result in vegetation patterns that mimic those found in higher elevation mesic soil temperature regimes, even in the adjoining MLRA 22A (Sierra Nevada Mountains). The most common soil map unit component by acreage is the Sierra component. This component is a very deep, fine-loamy mixed, active, thermic Ultic Haploxeralf derived from intrusive igneous parent material. This ecological site is not restricted to a specific geology, it also occurs on phyllite, schist, and other metasedimentary soils, especially Deerflat components, which are also very deep.

The dominant vegetation in this ecological site consists of dense forests (mean canopy cover ~ 51%) with species such as California black oak (Quercus kelloggii), interior live oak (Quercus wislizeni) and scattered ponderosa pine (Pinus ponderosa). Toyon (Heteromeles arbutifolia), manzanita (Arctostaphylos spp.), dense poison oak (Toxicodendron diversilobum), and sparse to moderately dense herbaceous annual forbs and grasses also occupy this site. This ecological site often hosts native perennial bunch grasses at 0 to 2 % cover. Herbaceous annual production generally makes up less than 2% of total production, and trees/and or shrubs exceed 90% of total annual production.

Elevation	800–3,000 ft	

Climatic features

Mean annual precipitation generally ranges from 32 to 38 inches. The majority of precipitation occurs between December and April. Temperatures range from a normal monthly minimum of 30.5 in December to a normal monthly maximum of 61.5 in July. See MLRA notes and LRU notes for general climate patterns of the area.

Influencing water features

Due to the topographic position, this site does not have water features or wetlands.

Wetland description

N/A

Soil features

The soils correlated to this ecological site are derived from colluvium and residuum weathered from metasedimentary and intrusive igneous rocks. These soils are deep to very deep and have fine-loamy particle size control sections with coarse sandy loam or gravelly loam surface textures. The bedrock is a restrictive layer that may be found in some pedons between 43 and 63 inches of depth. Rock fragments within the soil profile range from 3 to 23% gravels (< 3 inch diameter) and 0 to 1% larger fragments (=> 3 inch diameter). The soils in this ecological site are well drained and permeability is moderate. The Available Water Capacity (AWC) ranges from 5.2 to 6.2 inches and the pH range in the surface is from 5.5 to 6.1 and in the subsoil the pH ranges from 5.7 to 6.

Both Sierra and Deerflat components are fine-loamy mixed, active, thermic Ultic Haploxeralfs. Sierra is deep to very deep and Deerflat is a very deep soil.

Table 5. Representative soil features

Parent material	(1) Residuum–granitoid(2) Colluvium–metasedimentary rock(3) Residuum–metasedimentary rock(4) Colluvium–granitoid
Surface texture	(1) Coarse sandy loam (2) Gravelly loam
Family particle size	(1) Fine-loamy
Drainage class	Well drained
Permeability class	Moderate
Soil depth	43–63 in
Surface fragment cover <=3"	0%
Surface fragment cover >3"	0%
Available water capacity (0-40in)	5.2–6.2 in
Soil reaction (1:1 water) (0-10in)	5.5–6.1
Subsurface fragment volume <=3" (0-60in)	3–23%
Subsurface fragment volume >3" (0-60in)	0–1%

Table 6. Representative soil features (actual values)

Drainage class	Well drained
Permeability class	Moderately slow to moderate
Soil depth	30–79 in
Surface fragment cover <=3"	0%
Surface fragment cover >3"	0–2%
Available water capacity (0-40in)	3.8–7.6 in

Subsurface fragment volume <=3" (0-60in)	1–38%
Subsurface fragment volume >3" (0-60in)	0–33%

Ecological dynamics

Community pathways and Transitions

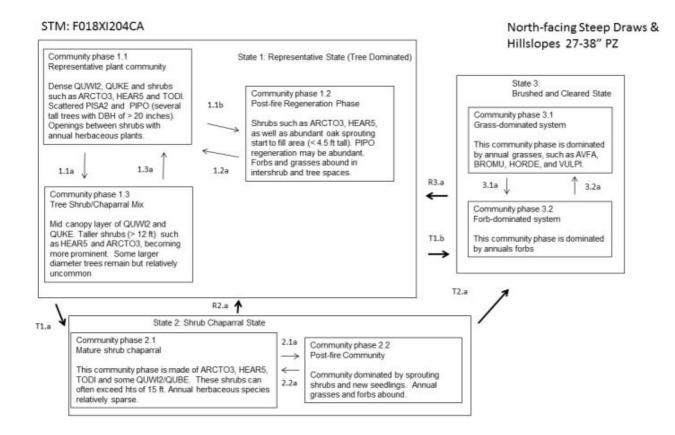

T1.a This transition occurs after decades of little to no disturbance (including management) which results in a build up of fuels. A high severity, stand replacing fire may then trigger an abrupt change to the vegetation composition and structure. Shrubs adapted to the new fire regime, sprout and seed at a much higher rate than the tree component, leading to a shrub chaparral state. Alternatively, drought driven losses of conifers (i.e. western pine beetle) can cause this transition to occur.

- T1.b This transition occurs after active brush management and enough browsing/grazing pressure to eliminate the woody vegetation.
- 1.1a Lack of disturbance, over time shrubs gain greater dominance.
- 1.1b This community pathway occurs with low to moderately severe fire promoting a sprouting response from trees. Alternatively, mechanical and prescribed burning can lead to an open woodland/pine community.
- 1.2a This community pathway occurs over time with no management action.
- 1.3a This community pathway occurs with moderate intensity, often patchy, fire which creates openings where grasses and forbs can populate. Mid canopy layers and shrubs are also reduced. This community pathway also can result with firewood cutting, or shrub clearing.
- T2.a This transition occurs after active brush management (and/or failed tree plantings) and enough browsing/grazing pressure to maintain an open shrub free system.
- R2.a This restoration pathway occurs after active brush management, chemical treatment, followed up with tree planting.
- 2.1a This community pathway occurs following a high intensity wildfire.
- 2.2a This community pathway occurs over time with no management action.
- R3.a This restoration pathway occurs with tree planting, often requiring shade screens and seedling protection from browsers to be successful.
- 3.1a This community pathway occurs as forbs become more dominant, often following low winter precipitation and reduced litter layers.
- 3.2a This community pathway occurs with ongoing brush management and/or active grazing management.

State and transition model

Community pathways and Transitions

- T1.a This transition occurs after decades of little to no disturbance (including management) which results in a build up of fuels. A high severity, stand replacing fire may then trigger an abrupt change to the vegetation composition and structure. Shrubs adapted to the new fire regime, sprout and seed at a much higher rate than the tree component, leading to a shrub chaparral state. Alternatively, drought driven losses of conifers (i.e. western pine beetle) can cause this transition to occur.
- T1.b This transition occurs after active brush management and enough browsing/grazing pressure to eliminate the woody vegetation.

- 2.1a This community pathway occurs following a high intensity wildfire.
- 2.2a This community pathway occurs over time with no management action.
- R3.a This restoration pathway occurs with tree planting, often requiring shade screens and seedling protection from browsers to be successful.
- 3.1a This community pathway occurs as forbs become more dominant, often following low winter precipitation and reduced litter layers.
- 3.2a This community pathway occurs with ongoing brush management and/or active grazing management.

State 1
Representative State (Tree Dominated)

Community 1.1 Representative plant community

Dense QUWI2, QUKE and shrubs such as ARCTO3, HEAR5 and TODI. Scattered PISA2 and PIPO (several tall trees with DBH of > 20 inches). Openings between shrubs with annual herbaceous plants.

Community 1.2 Post-fire Regeneration Phase

Shrubs such as ARCTO3, HEAR5, as well as abundant oak sprouting start to fill area (< 4.5 ft tall). PIPO regeneration may be abundant. Forbs and grasses abound in intershrub and tree spaces.

Community 1.3
Tree Shrub/Chaparral Mix

Mid canopy layer of QUWI2 and QUKE. Taller shrubs (> 12 ft) such as HEAR5 and ARCTO3, becoming more prominent. Some larger diameter trees remain but relatively uncommon

Pathway 1.1b Community 1.1 to 1.2

This community pathway occurs with low to moderately severe fire promoting a sprouting response from trees. Alternatively, mechanical and prescribed burning can lead to an open woodland/pine community.

Pathway 1.1a Community 1.1 to 1.3

Lack of disturbance, over time shrubs gain greater dominance.

Pathway 1.2a Community 1.2 to 1.1

This community pathway occurs over time with no management action.

Pathway 1.3a Community 1.3 to 1.1

This community pathway occurs with moderate intensity, often patchy, fire which creates openings where grasses and forbs can populate. Mid canopy layers and shrubs are also reduced. This community pathway also can result with firewood cutting, or shrub clearing.

State 2 Shrub Chaparral State

Community 2.1 Mature shrub chaparral

This community phase is made of ARCTO3, HEAR5, TODI and some QUWI2/QUBE. These shrubs can often exceed hts of 15 ft. Annual herbaceous species relatively sparse.

Community 2.2 Post-fire Community

Community dominated by sprouting shrubs and new seedlings. Annual grasses and forbs abound.

Pathway 2.1a Community 2.1 to 2.2

This community pathway occurs following a high intensity wildfire.

Pathway 2.2a Community 2.2 to 2.1

This community pathway occurs over time with no management action.

State 3
Brushed and Cleared State

Community 3.1 Grass-dominated system

This community phase is dominated by annual grasses, such as AVFA, BROMU, HORDE, and VULPI.

Community 3.2 Forb-dominated system

This community phase is dominated by annuals forbs

Pathway 3.1a Community 3.1 to 3.2

This community pathway occurs as forbs become more dominant, often following low winter precipitation and reduced litter layers.

Pathway 3.2a

Community 3.2 to 3.1

Forb-dominated system

Grass-dominated system

This community pathway occurs with ongoing brush management and/or active grazing management.

Transition T1.a State 1 to 2

This transition occurs after decades of little to no disturbance (including management) which results in a build up of fuels. A high severity, stand replacing fire may then trigger an abrupt change to the vegetation composition and structure. Shrubs adapted to the new fire regime, sprout and seed at a much higher rate than the tree component, leading to a shrub chaparral state. Alternatively, drought driven losses of conifers (i.e. western pine beetle) can cause this transition to occur.

Transition T1.b State 1 to 3

This transition occurs after active brush management and enough browsing/grazing pressure to eliminate the woody vegetation.

Restoration pathway R2.a State 2 to 1

This restoration pathway occurs after active brush management, chemical treatment, followed up with tree planting.

Transition T2.a State 2 to 3

This transition occurs after active brush management (and/or failed tree plantings) and enough browsing/grazing pressure to maintain an open shrub free system.

Restoration pathway R3.a State 3 to 1

This restoration pathway occurs with tree planting, often requiring shade screens and seedling protection from browsers to be successful.

Rangeland health reference sheet

Interpreting Indicators of Rangeland Health is a qualitative assessment protocol used to determine ecosystem condition based on benchmark characteristics described in the Reference Sheet. A suite of 17 (or more) indicators are typically considered in an assessment. The ecological site(s) representative of an assessment location must be known prior to applying the protocol and must be verified based on soils and climate. Current plant community cannot be used to identify the ecological site.
