Rangeland health reference sheet

Interpreting Indicators of Rangeland Health is a qualitative assessment protocol used to determine ecosystem condition based on benchmark characteristics described in the Reference Sheet. A suite of 17 (or more) indicators are typically considered in an assessment. The ecological site(s) representative of an assessment location must be known prior to applying the protocol and must be verified based on soils and climate. Current plant community cannot be used to identify the ecological site.

Composition (Indicators 10 and 12) based on	Annual Production

Indicators

- 1. Number and extent of rills: Rills are not present in the reference condition.
- 2. Presence of water flow patterns: Water flow patterns are rare in the reference condition.
- 3. Number and height of erosional pedestals or terracettes: Pedestals are not evident in the reference condition.
- 4. Bare ground from Ecological Site Description or other studies (rock, litter, lichen, moss, plant canopy are not bare ground): Bare ground is less than 15 percent.
- 5. Number of gullies and erosion associated with gullies: Gullies are not present in the reference condition.
- 6. Extent of wind scoured, blowouts and/or depositional areas: Wind scoured, or depositional areas are not evident in the reference condition.

- 7. Amount of litter movement (describe size and distance expected to travel): Movement of fine herbaceous litter may occur within less than a foot from where it originated. Scurfpea species may tumble significant distances for seed dispersal.
- Soil surface (top few mm) resistance to erosion (stability values are averages most sites will show a range of values): Soil Surface Stable with Stability Ratings of 4-6 (both under canopy and bare). Abiotic crusts and/or root mats may be present. The A horizon is 4-7 inches thick.
- 9. Soil surface structure and SOM content (include type of structure and A-horizon color and thickness): Soil Structure at the surface is typically strong to medium fine granular. The A horizon should be 4-7 inches thick with color, when wet, typically ranging in Value of 3 or less and Chroma of 3 or less. Local geology may affect color in which it is important to reference the Official Series Description (OSD).
- 10. Effect of community phase composition (relative proportion of different functional groups) and spatial distribution on infiltration and runoff: Evenly distributed across the site, bunchgrasses improve infiltration while rhizomatous grass protects the surface from runoff forces. The Droughty ecological site is well drained and has a moderate infiltration rate. An even distribution of mid stature bunchgrasses, cool season shortgrasses, cool season rhizomatous grasses, forbs, and shrubs
- 11. Presence and thickness of compaction layer (usually none; describe soil profile features which may be mistaken for compaction on this site): A compaction layer is not present in the Reference State.
- 12. Functional/Structural Groups (list in order of descending dominance by above-ground annual-production or live foliar cover using symbols: >>, >, = to indicate much greater than, greater than, and equal to):

Dominant: Mid-statured, cool season, perennial bunchgrasses, primarily bluebunch wheatgrass, needle and thread, rough fescue, and green needlegrass

Sub-dominant: perennial shortgrasses and grasslikes > rhizomatous grasses ≥ shrubs = forbs

Other:

Additional:

- 13. Amount of plant mortality and decadence (include which functional groups are expected to show mortality or decadence): Mortality in herbaceous species is not evident. Species with bunch growth forms may have some natural mortality in centers.
- 14. Average percent litter cover (%) and depth (in): Total litter cover ranges from 30 to 40 percent. Most litter is irregularly distributed on the soil surface and is not at a measurable depth.

production): Average annual production is 1500. Low: 1200. High 1700 lbs per acre.

Production varies based on effective precipitation and natural variability of soil properties for this ecological site.

- 16. Potential invasive (including noxious) species (native and non-native). List species which BOTH characterize degraded states and have the potential to become a dominant or co-dominant species on the ecological site if their future establishment and growth is not actively controlled by management interventions. Species that become dominant for only one to several years (e.g., short-term response to drought or wildfire) are not invasive plants. Note that unlike other indicators, we are describing what is NOT expected in the reference state for the ecological site: Potential invasive (including noxious) species (native and non-native). Invasive species on this ecological site include (but not limited to) annual brome spp., spotted knapweed, yellow toadflax, leafy spurge, ventenata, dandelion, crested wheatgrass, Kentucky bluegrass, etc. Native species such as Rocky Mountain juniper, ponderosa pine, broom snakeweed, rabbitbrush, blue grama, Sandberg's bluegrass, etc. when their populations are significant enough to affect ecological function, indicate site condition departure.
- 17. **Perennial plant reproductive capability:** In the reference condition, all plants are vigorous enough for reproduction either by seed or rhizomes in order to balance natural mortality with species recruitment. Density of plants indicates that plants reproduce at level sufficient to fill available resource.
