

Ecological site R102CY044NE WET LAND

Last updated: 10/03/2024
Accessed: 11/24/2024

General information

Provisional. A provisional ecological site description has undergone quality control and quality assurance review. It contains a working state and transition model and enough information to identify the ecological site.

MLRA notes

Major Land Resource Area (MLRA): 102C—Loess Uplands

Most of this area is in the Dissected Till Plains part of the Central Lowland Province of the Interior Plains. This MLRA has broad, undulating to rolling ridgetops and hilly to steep valley sides. The valleys are generally narrow, but broad flood plains and terraces are along the major rivers and the large tributaries. Elevation ranges from 335 to 610 meters (1,100 to 2,000 feet) increasing from southeast to northwest. Peorian age loess covers most of the area with depths ranging from 2 to 20 meters (6 to 70 feet). Glacial till underlies the loess in most areas. Bedrock can be found at or near the surface predominantly along the Missouri River valley found on the eastern side of the MLRA, but some bedrock can also be found in the northern part of 102C in Minnesota and South Dakota. The soils are predominantly Mollisols but Entisols are prominent in the floodplains of the area. Nearly all the area is farmed with 70% of the area being used as cropland for corn and soybeans. Feed grains and hay crops are also grown. The major resource concerns are wind erosion, water erosion, maintenance of organic matter and soil tilth, and soil moisture management. (USDA/NRCS 2006)

Ecological site concept

This ecological site is a wetland with a seasonal high water table, poorly to very poorly drained soils and a reference community of sedges and rushes. The foremost diagnostic feature of this site is the seasonally high-water table from 0 to 51 centimeters (0 to 20 inches), with additional moisture received from higher adjacent areas as runoff. The high-water table and potential frequent ponding can limit the types of plants that can occupy these areas. This site mainly occurs on nearly level to gently sloping floodplains and stream terraces (0-6% slopes). A few areas are on upland drains or interdunal areas in uplands that can range up to 5% slopes. It usually receives runoff from adjacent sites, has a seasonally high-water table from November-May, may flood occasionally for a brief duration and may frequently pond to four inches. These are predominantly very deep, very poorly to poorly drained soils. The surface texture covers a wide range of silty, loamy, and sandy textures from 15 to 76 centimeters (6 to 30 inches) and the Subsurface Texture Groups are Fine, Fine-Loamy, Fine-Silty or Sandy from 30 to 203 centimeters (12 to 80 inches). The reference plant community consists of 80-95% grasses and grass-like, 5-10% forbs and 0-5% shrubs. Dominant grass-like include Hardstem bulrush, Broadleaf arrowhead and various other members of the sedge family (sedges, rushes, bulrushes and spikersedges).

Associated sites

R102CY046NE	Subirrigated Occurs on higher relief with a seasonally high-water table between 24 and 40 inches and a marked decrease in hydrophytic vegetation.
R102CY048NE	Loamy Overflow Occurs on surrounding higher areas.
R102CY045NE	WET SUBIRRIGATED Occurs on adjacent slightly higher area with seasonally high-water table between 0 and 20 inches with a slight decrease in hydrophytic vegetation.

Similar sites

R102CY043NE	SHALLOW MARSH Occurs most commonly on closed upland depressions. Similar vegetation and water tables / ponding.

Physiographic features

This site mainly occurs on nearly level to gently sloping floodplains and stream terraces (0-6% slopes). A few areas are on upland drains or interdunal areas in uplands that can range up to 5% slopes. It usually receives runoff from adjacent sites, has a seasonally high-water table from November-May, may flood occasionally for a brief duration and may pond frequently to a depth of four inches.

Table 2. Representative physiographic features

Landforms	(1) Flood plain (2) Swale (3) Terrace
Runoff class	Very low to low
Flooding duration	Extremely brief (0.1 to 4 hours) to brief (2 to 7 days)
Flooding frequency	None to frequent

Ponding frequency	None to frequent
Elevation	366–451 m
Slope	0–6%
Ponding depth	0–10 cm
Water table depth	0–51 cm
Aspect	Aspect is not a significant factor

Climatic features

Most of the rainfall occurs as high-intensity, convective thunderstorms during the growing season. The maximum precipitation occurs from the middle of spring to early in autumn. Precipitation in winter occurs as snow. The annual snowfall ranges from about 60 centimeters (24 inches) in the southern part of the area to 85 centimeters (34 inches) in the northern part. The average annual temperature gradient trends higher from north (45°F) to south (51°F), and the average annual precipitation gradient trends higher from northwest (25") to southeast (31").

The following data summary includes weather stations representing the full geographic extent of the MLRA and is based on 70% probabilities. This means that actual observed climate conditions may fall outside these ranges 30% of the time. Furthermore, climatic events can manifest many ways. For example, abnormally dry periods could occur as 3 consecutive drought years out of 10, 3 individual years separated by “normal” years, or some combination. Tree-ring records indicate that portions of the Great Plains have also historically experienced droughts lasting several decades, so plant community response will largely depend on the way climatic variability is realized in interaction with past and current land management.

Influencing water features

This site has a seasonal high-water table from November to May and may flood occasionally for a brief duration.

Soil features

These are predominantly very deep, very poorly to poorly drained soils. The surface texture covers a wide range of silty, loamy, and sandy textures from 15 to 76 centimeters (6 to 30 inches) and the Subsurface Texture Groups are Fine, Fine-Loamy, Fine-Silty or Sandy from 30 to 203 centimeters (12 to 80 inches). Rills, gullies, and water flow patterns are not inherent to this site. Pedestalling is none to slight. Soil aggregate stability will vary based on the varying textural classes in this ecological site.

Major soils assigned to this site include: Calco, Arlo, Barney, Kezan, James, Loup, Zook, Baltic, Norway, Clarno, Clamo, Colo and Lamo.

Table 4. Representative soil features

Parent material	(1) Alluvium
Surface texture	(1) Silt loam (2) Loam (3) Fine sandy loam (4) Loamy fine sand (5) Silty clay loam
Drainage class	Very poorly drained to poorly drained
Permeability class	Very slow to rapid
Soil depth	203 cm
Surface fragment cover <=3"	0%
Surface fragment cover >3"	0%
Available water capacity (Depth not specified)	2.54–22.86 cm
Calcium carbonate equivalent (Depth not specified)	0–40%
Electrical conductivity (Depth not specified)	0–8 mmhos/cm

Sodium adsorption ratio (Depth not specified)	0–15
Soil reaction (1:1 water) (Depth not specified)	5.6–9
Subsurface fragment volume <=3" (Depth not specified)	0%
Subsurface fragment volume >3" (Depth not specified)	0%

Ecological dynamics

The foremost diagnostic feature of this site is the seasonally high-water table from 0 to 51 centimeters (0 to 20 inches), with additional moisture received from higher adjacent areas as run-on. The high-water table and ponding can limit the types of plants that can occupy these areas but also can “buffer” variability in plant production caused by fluctuating weather conditions (droughts). Relatively minor changes in local elevation can dramatically affect the plant community due to changes in the depth to the water table. This site often occurs in complex with other sites, particularly Wet Land, Subirrigated, and Loamy Overflow. Plant community composition may also experience similar changes through disturbances that affect the water table itself, such as extended dry or wet cycles.

This site developed with occasional fires being part of the ecological processes. It is presumed that the historic fires generally occurred every 3-4 years, were randomly distributed, and started by lightning at various times throughout the season when thunderstorms were likely to occur. It is also believed that pre-European inhabitants may have used fire as a management tool for attracting herds of large migratory herbivores (bison, elk, and/or deer.) The impact of fire over the past 100 years has been relatively insignificant due to the human control of wildfires and the lack of acceptance of prescribed fire as a management tool.

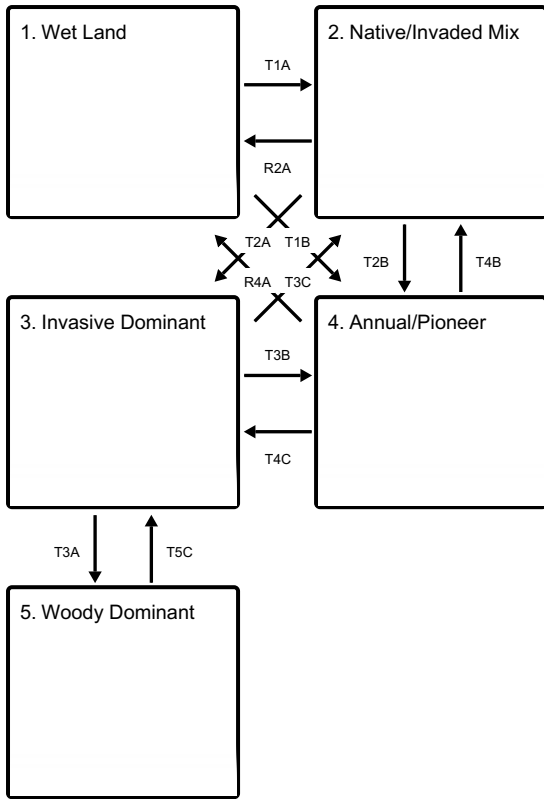

The degree of herbivory (feeding on herbaceous plants) has a significant impact on the dynamics of the site. Historically, periodic grazing by herds of large migratory herbivores was a primary influence. Secondary influences of herbivory by species such as grasshoppers and root feeding organisms impacted the vegetation historically and continue to this day. The management of herbivory by humans through grazing of domestic livestock and/or manipulation of wildlife populations has been a major influence on the ecological dynamics of the site. This management coupled with climate largely dictates the plant communities for the site.

The plant community for this site is dynamic due to the complex interaction of many ecological processes. The interpretive plant community for this site is the reference state. The reference state has been determined by the study of rangeland relic areas, areas protected from excessive disturbance and areas under long term rotational grazing strategies. Trends in plant community dynamics ranging from heavily grazed to lightly grazed areas, seasonal use pastures, and historical accounts have also been used.

The following is a diagram that illustrates the common plant communities that can occur on the site and the transition pathways among communities. The ecological processes will be discussed in more detail in the plant community descriptions following the diagram.

State and transition model

Ecosystem states

States 1, 5 and 2 (additional transitions)

T1A - Disturbance; colonization of reed canarygrass

T1B - Severe disturbance makes resources available to opportunistic species.

T1C - Woody encroachment leading to woody dominance

R2A - Reduced invasive grass competitiveness allows natives to reclaim resources.

T2A - Reduced native competitiveness allow for introduced grass colonization and expansion.

T2B - Severe disturbance makes resources available to opportunistic species.

T2C - Woody encroachment leading to woody dominance

T3C - Reduced invasive grass competitiveness allows natives to reclaim resources.

T3B - Severe disturbance makes resources available to opportunistic species.

T3A - Woody encroachment

R4A - Successional processes tie up resources in a more stable community

T4B - Successional processes tie up resources in a more stable community

T4C - Successional processes tie up resources in a more stable community

R5A - Woody removal for return to herbaceous dominance

T5B - Woody removal for return to herbaceous dominance

T5C - Woody removal for return to herbaceous dominance

State 1 submodel, plant communities

1.1A - Reduced tallgrass vigor due to excessive defoliation intensity and frequency; drought.

1.2A - Improved tallgrass vigor with adequate rest periods; return of normal precipitation.

State 2 submodel, plant communities

2.1A - Reduced native competitiveness allow for introduced grass colonization and expansion.

2.2A - Reduced invasive grass competitiveness allows natives to reclaim resources.

State 3 submodel, plant communities

State 4 submodel, plant communities

State 5 submodel, plant communities

State 1 Wet Land

This state comprises the communities within the range of natural variability under historic conditions and disturbance regimes. Patterns created by wildlife use and fire would have created a mosaic of communities across the landscape; however, warm-season tallgrasses are dominant, with a subdominant to minor contribution from native cool- season grasses, forbs, and shrubs. Fire and bison herbivory were the dominant disturbance regimes that historically maintained the tallgrass dominance with a diverse forb component. Furthermore, bison grazing was closely linked to fire patterns as the animals preferred grazing burned areas offering lush regrowth devoid of decadence and of higher nutritive quality. Thus, historic plant communities were subjected to occasional burning and grazing, with substantial rest/recovery periods as the fuel load rebuilt to eventually start this process again. Fire return intervals of 3-4 years served to suppress woody species, particularly the various tree and shrub species prevalent in adjacent riparian corridors. The degree to which observed conditions represent this state largely depends on how closely the management has mimicked these past disturbance effects.

Dominant plant species

- prairie cordgrass (*Spartina pectinata*), grass
- hardstem bulrush (*Schoenoplectus acutus*), grass
- northern reedgrass (*Calamagrostis stricta* ssp. *inexpansa*), grass
- broadleaf arrowhead (*Sagittaria latifolia*), other herbaceous

Community 1.1

Hardstem bulrush – Broadleaf arrowhead (*Schoenoplectus acutus* - *Sagittaria latifolia*)

This is the interpretive plant community and can be found on areas that are properly managed with prescribed grazing that allows for adequate recovery periods following each grazing event. The plant community consists of 80-95% grasses and grass-like, 5-10% forbs and 0-5% shrubs. Dominant grass-like include Hardstem bulrush, Broadleaf arrowhead and various other members of the sedge family (sedges, rushes, bulrushes and spikesedges). Other grasses and grass-like are Big bluestem, Bluejoint, Northern reedgrass, Plains bluegrass. This plant community is diverse, stable, and productive. Plant community dynamics, nutrient cycles, water cycles, and energy flow are functioning properly. Plant litter is properly distributed with negligible movement off-site and natural plant mortality is very low. This community is resistant to many disturbances except continuous, season-long heavy grazing, tillage, or non-use. Broadcast herbicide application will dramatically reduce forb diversity and abundance. Total annual production, during an average year, ranges from 3,000 to 6,000 pounds per acre air-dry weight. (USDA/NRCS 2012)

Dominant plant species

- northern reedgrass (*Calamagrostis stricta* ssp. *inexpansa*), grass
- prairie cordgrass (*Spartina pectinata*), grass
- hardstem bulrush (*Schoenoplectus acutus*), grass
- broadleaf arrowhead (*Sagittaria latifolia*), other herbaceous

Community 1.2

Water smartweed – Nodding beggartick (*Persicaria amphibia* – *Bidens cernua*)

Water knotweed and Nodding beggartick have replaced Hardstem bulrush as the dominant species. Other species, such as Reed canarygrass have also increased. While still within the range of natural variability, energy capture, nutrient cycling, and hydrology are not functioning at their full potential relative to the reference condition. Native warm seasons have decreased in the southern part of the MLRA.

Pathway 1.1A

Community 1.1 to 1.2

Grazing management which does not provide adequate recovery periods will cause a shift from towards less palatable species.

Pathway 1.2A

Community 1.2 to 1.1

Management that provides adequate recovery periods and does not annually prevent tallgrass seed set or otherwise impair vigor will facilitate a return to community phase 1.1. In the case of drought, the return to more typical precipitation patterns will promote shift towards reference species.

State 2

Native/Invaded Mix

This state can manifest in three ways: 1) the appearance of cool-season introduced grasses, 2) the expansion of shrubs and/or trees, or 3) some combination of these. Kentucky bluegrass and Smooth brome are the primary cool-season grass invaders in this region, commonly found in roadsides, disturbed areas, and pastures intentionally seeded for cool-season forage. Management practices and/or environmental conditions that are not favorable to native grass vigor may allow introduced grasses to invade the site thereby decreasing native diversity and abundance, particularly of forbs. While Reed canarygrass is a native, it may act in much the same way as the introduced species and is the main invader of the wetland sites. In the absence of the historic fire regime, woody species may also expand to become an influential component of the community. The invasive component tends to have very high resilience, is extremely difficult to eradicate, and what might be considered a new "contemporary" range of natural variability is seen as competition between the native grasses and introduced/woody species for space and resources.

Dominant plant species

- reed canarygrass (*Phalaris arundinacea*), grass
- smooth brome (*Bromus inermis*), grass
- Kentucky bluegrass (*Poa pratensis*), grass

Community 2.1

Subdominant Reed canarygrass (*Phalaris arundinacea*)

While native grasses and grass-like species still dominate the site, introduced cool-season species have established a foothold in the system and can be found interspersed throughout the stand. The stand may still have a native tallgrass appearance overall, but Reed canarygrass can be easily found. Shrub/tree species may also have begun to expand into areas where they did not persist historically, but the overall appearance can vary depending on the propagation method of a particular species.

Dominant plant species

- smooth brome (*Bromus inermis*), grass
- reed canarygrass (*Phalaris arundinacea*), grass
- Kentucky bluegrass (*Poa pratensis*), grass

Community 2.2

Codominant Reed canarygrass (*Phalaris arundinacea*)

This community is comprised of a relatively even mix of native grasses and invasive species overall. This may manifest as a well-distributed interspersion of natives and invaders, as distinct patches wherein competitors dominate locally, or some combination. Forb diversity and abundance is further diminished.

Dominant plant species

- reed canarygrass (*Phalaris arundinacea*), grass
- smooth brome (*Bromus inermis*), grass
- Kentucky bluegrass (*Poa pratensis*), grass

Pathway 2.1A

Community 2.1 to 2.2

Management and/or environmental conditions have afforded a persisting competitive advantage to introduced cool-season grasses, and they begin to dominate the ecological dynamics of the site. The robust invasive component can quickly and effectively exploit opportunities to outcompete and displace natives. Repeated summer use of an area will place the bulk of stressor impacts on native plants, reducing native vigor and allowing invaders to thrive. Likewise, a climate pattern limiting natural moisture to the spring and fall months coincides with peak cool-season growth and may support a similar process.

Pathway 2.2A

Community 2.2 to 2.1

The native component remains in an abundance that can facilitate a return towards more historic conditions if management is modified to shift stressor impacts to the invasive species and promote warm-season grass vigor. Environmental conditions and/or disturbance regimes that strongly favor warm-season grasses can also trend the site towards the reference.

State 3

Invasive Dominant

Introduced cool-season invasion has progressed to the point that native species comprise a negligible portion of the community and the aggressively rhizomatous invasives preclude native germination and seedling survival. The native component may be completely absent, and the site resembles a seeded pasture. Alternatively, the dominant

invasives may be woody species. Woody competitiveness for sunlight, water, space, and other resources continues to increase as desirable herbaceous species are shaded out, crowded out, or otherwise suppressed.

Dominant plant species

- smooth brome (*Bromus inermis*), grass
- Kentucky bluegrass (*Poa pratensis*), grass
- reed canarygrass (*Phalaris arundinacea*), grass

Community 3.1

Reed canarygrass (*Phalaris arundinacea*)

This community is typically composed of cool-season invasive species. Warm-season natives, if present, are sparse yet often conspicuous due to pronounced differences in growth habits and metabolic pathways.

Dominant plant species

- reed canarygrass (*Phalaris arundinacea*), grass

State 4

Annual/Pioneer

Nutrient cycling, hydrologic function, and/or soil stability have been severely altered, and possibly compromised. This is a highly variable state in which the specific plants observed will depend largely on the original community and the nature of the disturbance. This condition encompasses (but is not necessarily limited to) events such as severe fire impacts, heavy continuous grazing, heavy nutrient inputs, and abandoned cropland.

Dominant plant species

- leafy spurge (*Euphorbia esula*), other herbaceous
- Canada thistle (*Cirsium arvense*), other herbaceous

Community 4.1

Variable native and introduced

This community is heavily dominated by annual plants that thrive in disturbed areas. It is also particularly vulnerable to noxious weed invasion with the most common species being Leafy spurge, Musk and Canada thistles.

Dominant plant species

- leafy spurge (*Euphorbia esula*), other herbaceous
- Canada thistle (*Cirsium arvense*), other herbaceous

State 5

Woody Dominant

Under historic disturbance regimes, frequent and uncontrolled fire and wildlife browsing served to keep woody species in check. However, in the absence of fire (either wild or prescribed), it's not uncommon for the woody trees and shrubs normally limited to riparian areas to expand into the floodplains, regardless of herbaceous community composition. Wildlife may introduce a seed source to areas not associated with a waterway, such as interdunal depressions.

Dominant plant species

- willow (*Salix*), tree
- maple (*Acer*), tree
- eastern cottonwood (*Populus deltoides*), tree

Community 5.1

Native deciduous overstory

Woody species have encroached and established, typically with species such as maples, cottonwood, boxelder, green ash, willow and swamp oak.

Dominant plant species

- willow (*Salix*), tree
- maple (*Acer*), tree
- eastern cottonwood (*Populus deltoides*), tree

Transition T1A

State 1 to 2

In the presence of environmental conditions and/or management that reduces native vigor and stand resilience, and frees up resources (space, sunlight, nutrients, water) will allow for colonization of Reed canarygrass. Likewise, similar processes may also allow for woody species to expand, particularly willows and cottonwoods.

Transition T1B

State 1 to 4

There are many possible triggers for this transition that may occur as acute events (e.g. plowing) or cumulative impacts of chronic events (e.g. long-term undermanaged grazing.) The absence of deep-rooted perennial cover exposes the site to topsoil loss, open nutrient cycle, and free space which collectively allow for opportunistic annual species to dominate.

Transition T1C

State 1 to 5

All herbaceous communities are vulnerable to woody encroachment in the absence of fire and/or browsing and hoof action impacts. This is particularly prominent in areas adjacent to riparian corridors which supply a constant seed source. As tree establishment progresses, the conditions grow increasingly favorable for woody germination and growth.

Restoration pathway R2A

State 2 to 1

Eradication of introduced cool-season grasses from this site will require long-term, targeted management efforts to create an adverse environment during the spring and late fall when cool season species are most actively growing, with favorable conditions during the summer to promote native warm-season species. Targeted practices such as prescribed burning, flash grazing, and herbicide are often employed at strategic times of the year to set back undesirable species. The combination of practices should strive to mimic the historic disturbance regimes to which the desirable native species are best adapted.

Transition T2A

State 2 to 3

If the conditions which initiated and fomented the colonization and expansion of cool- season invasion are not removed or mitigated, stand composition will continue to shift in this direction and begin to resemble a monoculture. Due to the dense rhizomatous root mat of many invasive species, native species suffer decreasing opportunities to contribute propagules, and individual plants lost are not replaced by desirable natives.

Transition T2B

State 2 to 4

There are many possible triggers for this transition that may occur as acute events (e.g. plowing) or cumulative impacts of chronic events (e.g. long-term undermanaged grazing.) The absence of deep-rooted perennial cover exposes the site to topsoil loss, open nutrient cycle, and free space which collectively allow for opportunistic annual

species to dominate.

Transition T2C

State 2 to 5

All herbaceous communities are vulnerable to woody encroachment in the absence of fire and/or browsing impacts. This is particularly prominent in areas adjacent to riparian corridors which supply a constant seed source. As tree establishment progresses, the conditions grow increasingly favorable for woody germination and growth.

Restoration pathway T3C

State 3 to 2

Aggressive intervening actions will be required to simultaneously recolonize native grasses and suppress vigor in undesirable species. Restoration follows the same principles as the R2A pathway but may also require native range seeding if the latent seedbank is inadequate.

Transition T3B

State 3 to 4

Nutrient cycling, hydrologic function, and/or soil stability have been severely altered, and possibly compromised. This is a highly variable state in which the specific plants observed will depend largely on the original community and the nature of the disturbance.

Transition T3A

State 3 to 5

All herbaceous communities are vulnerable to woody encroachment in the absence of fire and/or browsing impacts. This is particularly prominent in areas adjacent to riparian corridors which supply a constant seed source. As tree establishment progresses, the conditions grow increasingly favorable for woody germination and growth.

Restoration pathway R4A

State 4 to 1

Restoration strategies will depend on the nature of the disturbance and the viability of the seedbank. On pastures, changes to grazing management and favorable moisture conditions may produce a perennial community. However, in abandoned cropland range seeding will likely be necessary to recolonize desirable perennial species.

Restoration pathway T4B

State 4 to 2

As the site matures from the annual / pioneer stage, it will transition over to a mix of native and invaded species depending on the seed sources available. In many cases this will be Reed canarygrass for these sites.

Restoration pathway T4C

State 4 to 3

The annual / pioneer stage can transition to an invasive dominant stage if the seed source available after the disturbance is predominantly non-native species.

Restoration pathway R5A

State 5 to 1

The combination of tree size, reduced herbaceous understory, and more mesic conditions makes it increasingly difficult for natural disturbances to restore/maintain the historic tallgrass community, and mature woodlands can no longer be restored with fire. Intensive brush management will be required to mechanically remove the established overstory. Woody control and maintenance will be an ongoing process and may also require chemical methods if sprouting species are present.

Restoration pathway T5B

State 5 to 2

Any type of natural act or management practices that kill off the woody species can transition the woody dominant site back to a native / invaded mix as the remaining herbaceous plants and seed source thrive due to the introduction of more sunlight and less woody competition.

Restoration pathway T5C

State 5 to 3

Any type of natural act or management practices that kill off the woody species can transition the woody dominant site back to invasive dominant regime as the remaining herbaceous plants and seed source thrive due to the introduction of more sunlight and less woody competition.

Additional community tables

Inventory data references

Information presented here has been derived from RANGE-417 archives, Rangeland NRI, and other inventory data. Meetings and comments of local, state and regional experts convene and created the ES concepts and STMs. Field observations from range-trained personnel were also used. Field observations from range-trained personnel were also used. In addition to the multitude of NRCS field office employees and private landowners that helped with site visits and local knowledge, those involved in developing this site include:

Nebraska NRCS:

Nadine Bishop, State Rangeland Management Specialist
Patrick Cowsert, Resource Soil Scientist
Cassidy Gerdes, Biologist
Dirk Schultz, Soil Conservationist
Dan Shurtliff, Asst. State Soil Scientist (retired)

South Dakota NRCS:

Stan Boltz, State Rangeland Management Specialist
Shane Deranleau, Area Rangeland Management Specialist
Kevin Luebke, State Biologist

Iowa NRCS:

Jess Jackson, Area Grazing Specialist

Minnesota NRCS:

Lance Smith, Area Grazing Specialist

MLRA Office 10:

Stu McFarland, Ecological Site Inventory Specialist
Stacey Clark, Ecological Site Inventory Specialist, QA
Michael Whited, Region 10 Director (retired)
Jo Parsley, Soil Scientist/ Soil Data Quality Specialist

National Soil Survey Center:

Mike Kucera, National Agronomist, Soil Quality & Ecosystems
Steve Peaslee, GIS Specialist, Soil Survey Interpretations

Nebraska Game & Parks Commission:

Gerry Steinauer, Botanist
Scott Wessel, Biologist
Russ Hamer, Biologist
Rebekah Jessen, Biologist

Nebraska Forest Service:
Steve Rasmussen, District Forester

Rangeland health reference sheet

Interpreting Indicators of Rangeland Health is a qualitative assessment protocol used to determine ecosystem

condition based on benchmark characteristics described in the Reference Sheet. A suite of 17 (or more) indicators are typically considered in an assessment. The ecological site(s) representative of an assessment location must be known prior to applying the protocol and must be verified based on soils and climate. Current plant community cannot be used to identify the ecological site.

Composition (Indicators 10 and 12) based on	Annual Production

Indicators

1. **Number and extent of rills:**

2. **Presence of water flow patterns:**

3. **Number and height of erosional pedestals or terracettes:**

4. **Bare ground from Ecological Site Description or other studies (rock, litter, lichen, moss, plant canopy are not bare ground):**

5. **Number of gullies and erosion associated with gullies:**

6. **Extent of wind scoured, blowouts and/or depositional areas:**

7. **Amount of litter movement (describe size and distance expected to travel):**

8. **Soil surface (top few mm) resistance to erosion (stability values are averages - most sites will show a range of values):**

9. **Soil surface structure and SOM content (include type of structure and A-horizon color and thickness):**

10. **Effect of community phase composition (relative proportion of different functional groups) and spatial distribution on infiltration and runoff:**

11. **Presence and thickness of compaction layer (usually none; describe soil profile features which may be mistaken for compaction on this site):**

12. **Functional/Structural Groups (list in order of descending dominance by above-ground annual-production or live foliar cover using symbols: >>, >, = to indicate much greater than, greater than, and equal to):**

Dominant:

Sub-dominant:

Other:

Additional:

13. **Amount of plant mortality and decadence (include which functional groups are expected to show mortality or decadence):**

14. **Average percent litter cover (%) and depth (in):**

15. **Expected annual annual-production (this is TOTAL above-ground annual-production, not just forage annual-production):**

16. **Potential invasive (including noxious) species (native and non-native). List species which BOTH characterize degraded states and have the potential to become a dominant or co-dominant species on the ecological site if their future establishment and growth is not actively controlled by management interventions. Species that become dominant for only one to several years (e.g., short-term response to drought or wildfire) are not invasive plants. Note that unlike other indicators, we are describing what is NOT expected in the reference state for the ecological site:**

17. **Perennial plant reproductive capability:**
