

Ecological site VX164X01X501 Sphagnum Peat Dwarf Forest

Accessed: 04/25/2024

General information

Provisional. A provisional ecological site description has undergone quality control and quality assurance review. It contains a working state and transition model and enough information to identify the ecological site.

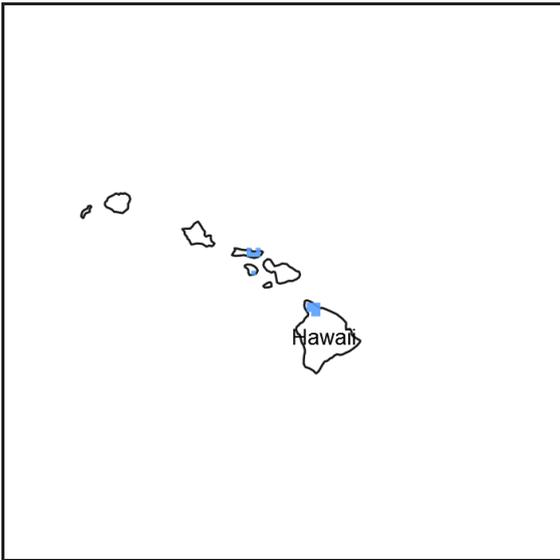

Figure 1. Mapped extent

Areas shown in blue indicate the maximum mapped extent of this ecological site. Other ecological sites likely occur within the highlighted areas. It is also possible for this ecological site to occur outside of highlighted areas if detailed soil survey has not been completed or recently updated.

MLRA notes

Major Land Resource Area (MLRA): 164X–Humid and Very Humid Steep and Very Steep Mountain Slopes

This MLRA occurs in the State of Hawaii on the islands of Hawaii, Maui, Molokai, Oahu, and Kauai. It consists primarily of deeply dissected mountainous areas. Elevation ranges from sea level to 7,000 feet (0 to 2100 meters). Topography is mostly steep, with ridges, gulches, and canyons, as well as areas of plateau. Underlying geology is fractured, basic, igneous rock (mostly basalt) that is slightly to highly weathered. Over this are found deposits of local volcanic ash, tropospheric dust from Asia, and/or organic deposits. Climate is mostly wet tropical. Average annual precipitation typically ranges from 75 to 250 inches (1875 to 6250 millimeters), with extremes of 30 to 450 inches (750 to 11,250 millimeters). Rainfall is well distributed throughout the year with an enhanced rainy season from November through April. Fog drip can add significant amounts of water to the soil. Average annual temperatures range from 53 to 75 degrees F (12 to 24 degrees C), with very little seasonal variation. Soils are mostly Inceptisols, Andisols, and Histosols with isothermic or isomesic soil temperature regimes. Native vegetation consists of moderate stature rainforests and dwarf forests.

Classification relationships

This ecological site occurs within Major Land Resource Area (MLRA) 164 - Humid and Very Humid Steep and Very Steep Mountain Slopes.

Ecological site concept

This ecological site is a very wet, boggy dwarf forest that exists on top of Kohala Mountain. The area is owned by the State of Hawaii. No public roads provide access to this ecological site.

This ecological site, or related ecological sites, also may occur on Maui, Molokai, Oahu, and Kauai; field work has yet to be completed. Based on existing information, soil and vegetation differences may result in related ecological sites on the other islands.

The central concept of the Sphagnum Peat Dwarf Forest is of poorly drained, deep soils formed in deposits of volcanic ash that are covered with a layer of peat. Lava flows range from 120,000 to 500,000 years old. Annual air temperatures and rainfall interacting with a dense ironstone horizon create warm (isothermic), water saturated and anaerobic (aquic) soil conditions. These soils support a dwarf forest with an overstory of ohia lehua (*Metrosideros polymorpha*) and olapa (*Cheirodendron trigynum*) from 3 to 16 feet (1 to 5 meters) tall and a very diverse understory of trees, shrubs, tree ferns, forbs, grasses, sedges, and ferns. There is usually a thick growth of mosses, liverworts, and small ferns on tree trunks. The ground is covered with a thick layer of sphagnum moss in which the plant species are rooted.

Physiographic features

This ecological site occurs on volcanic ash flows deposited over lava flows on sloping mountainsides of shield volcanoes, on interfluves of steep dissected uplands on middle elevation, windward mountain slopes. Volcanic ash flows range are shallow on the underlying lava.

Climatic features

There are no climate stations near this ecological site with complete data sets suitable for automatically filling the data boxes and charts below.

The estimates in the following text are based on modeled climate maps and incomplete and/or historic data sets from multiple stations compiled by NRCS Hawaii Soil Survey.

Average annual precipitation ranges from 75 to 400 inches (1905 to 10,160 millimeters). Rainfall occurs throughout the year, with the heaviest precipitation occurring from October through April. Landscapes are shrouded in fog or overcast during much of the day throughout the year, which reduces evapotranspiration and adds additional moisture from condensation of fog on vegetation. Mean annual soil temperature ranges from 57 to 61 degrees F (14 to 16 degrees C). Frost free and freeze free periods are 365 days per year.

Table 3. Representative climatic features

Frost-free period (average)	0 days
Freeze-free period (average)	0 days
Precipitation total (average)	0 in

Influencing water features

Streams exist in shallow to deep gulches. Vegetation and soils immediately next to the streams vary little from those of the rest of the ecological site.

Soil features

This ecological site is correlated only with Amalu peat. This soil series formed in organic matter over basic volcanic ash and tropospheric dust over residuum weathered from basalt. Landscape surfaces in this ecological site are the oldest on the Island of Hawaii (120,000 to 500,000 years old). Soil temperature regimes are isomesic. Soil moisture regimes are aquic, which is a reducing regime in a soil that is virtually free of dissolved oxygen because it is saturated by water.

The organic peat surface horizon is typically about 8 inches (20 centimeters) thick. Directly beneath it is a gleyed (gray, reduced) mineral horizon. Plant roots appear to be primarily, and maybe exclusively, in the surface peat horizon.

Soils have a surface layer of live and decomposed sphagnum moss of variable thickness that typically is about 8 inches (20 cm) thick. Most live plant roots are found in this horizon. Below the sphagnum horizon is a layer of gleyed, anaerobic mineral soil. Beneath this layer is an ironstone pan that perches water and acts as a barrier to root penetration.

Ecological dynamics

The information in this ecological site description (ESD), including the state-and-transition model (STM), was developed using archaeological and historical data, professional experience, and scientific studies. The information is representative of a complex set of plant communities. Not all scenarios or plants are included. Key indicator plants, animals, and ecological processes are described to inform land management decisions.

Human-related disturbances have been much more important than natural disturbances in this ecological site since the arrival of Polynesians and, later, Europeans. This is reflected in the State and Transition Model Diagram.

Natural Disturbances

This ecological site has not been affected by local volcanic activity for hundreds of thousands of years. It is far enough from more recently active volcanoes on the island to have avoided heavy falls of volcanic ash within that time. Rainfall is very high, so wildfires do not occur. Vegetation is low in stature, so windfall is not an important factor.

Human Disturbances

Humans arrived in the Hawaiian Islands 1200 to 1500 years ago. Their population gradually increased so that by 1600 AD at least 80% of all the lands in Hawaii below about 1500 feet (roughly 500 meters) in elevation had been extensively altered by humans (Kirch 1982). This ecological site occurs well above that elevation. However, this ecological site affected by factors connected with the arrival of humans (Athens 1997).

The Polynesians introduced dogs, Pacific rats, and small pigs to the islands. Cattle, sheep, horses, goats, and larger European pigs were introduced in the final decades of the 18th century. These animals ranged free on the islands, becoming very numerous and destructive by the early decades of the 19th century (Henke 1929). The most destructive introduced animals in this relatively remote ecological site have been feral pigs and cattle.

After the arrival of Europeans, documentary evidence attests to accelerated and extensive deforestation, erosion, siltation, and changes in local weather patterns (Kirch 1983) due to more intensive land use, modern tools, and introduction of more plant, animal, and microbe species.

Through the 20th and into the 21st centuries, increases in human populations with attendant land development, as well as accelerated introduction of non-native mammals, birds, reptiles, amphibians, invertebrates, plants, and microorganisms, have brought about dramatic changes to wild ecosystems in Hawaii. Most of the original forest area of this ecological site remains fairly intact. However, the native plant community in many areas has been highly disturbed and in some places destroyed due to clearing, feral ungulate foraging, and invasion by introduced species. Introduced plant species are capable of completely and permanently replacing native vegetation.

State and transition model

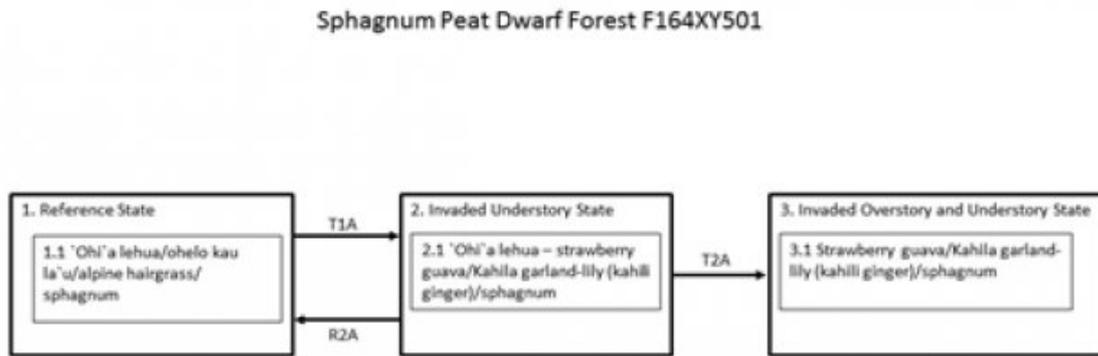

Figure 4. State and Transition Diagram F164XY501

State 1 Reference State

The Reference State consists of one community phase. Under a regime of natural disturbances, this community has probably been stable through post-glacial time frames. State 1 will transition into State 2 Invaded Understory by clearing and abandonment or by gradual weed invasion, which is exacerbated by feral ungulates.

Community 1.1 `Ōhi`a lehua/ohelo kau la`u/alpine hairgrass/sphagnum

Figure 5. Reference community state. 11/1/06 D Clausnitzer MU426

Figure 12. Site with taller trees. 8/8/06 D Clausnitzer MU426

Figure 13. Transition upslope to F164XY500. 8/8/06 D Clausnitzer MU426

This community phase is a wetland with low stature trees, scattered tree ferns, and diverse shrubs, forbs, vines, grasses, and sedges. The soil surface is covered by a deep (1 to 2 feet or 30 to 45 centimeters) layer of sphagnum moss. The tallest plants typically range from 4 to 15 feet (1.3 to 4.6 meters) tall. In some areas, the overstory may be as short as 3 feet (1 meter) or as tall as 30 feet (9 meters). Trunks and branches of trees and shrub are covered by a heavy growth of mosses, liverworts, and small ferns. Most, if not all, the species occurring in the Reference State are typical of other Hawaiian moist forests.

Forest overstory. The tallest species are dwarfed ohia lehua (*Metrosideros polymorpha*) and olapa (*Cheirodendron trigynum*).

Forest understory. The understory is very diverse. Many typical Hawaiian forest tree species are found here, but are dwarfed in stature. Three tree fern species (*Cibotium glaucum*, *C. menziesii*, and *C. chamissoi*) are common but not abundant. The most common shrub is ohelo kau lau (*Vaccinium calycinum*). Uluhe (*Dicranopteris linearis*) forms small thickets or creeps between other vegetation. Small ferns are very diverse. Alpine hairgrass (*Deschampsia nubigena*) is common on the moss surface.

State 2 Invaded Understory State

This state consists of one community phase. Native plant abundance and diversity are lower than in the Reference state. Native species are unable to regenerate in this plant community and eventually die out. Some small native ferns persist on tree trunks and limbs. Ground cover of sphagnum moss is lower than in the Reference state. Where sphagnum cover is naturally shallow, digging and rooting by pigs removes the sphagnum cover completely, exposing the mineral soil beneath. These bare soil patches are easily invaded by introduced weed species.

Community 2.1

`Ohi`a lehua/strawberry guava/Kahila garland-lily (kahili ginger)/sphagnum

Figure 14. Understory invaded by kahili ginger. 11/8/06 D Clausnitzer MU426

This community phase has an intact or diminished overstory of native trees with a dense understory of native and introduced forbs, shrubs, ferns, grasses, and small trees.

Forest overstory. The overstory is still dominated by ohia lehua (*Metrosideros polymorpha*) and olapa (*Cheirodendron trigynum*).

Forest understory. Strawberry guava (*Psidium cattleianum*) is more abundant than native trees in the secondary canopy. Koster's curse (*Clidemia hirta*) and cane tibouchina (*Tibouchina herbacea*) are common. Kahili ginger can be particularly abundant, forming a dense ground cover and filling the soil surface with its roots. Strawberry guava can emerge through dense ginger stands. Grass canopy cover has increased from 5% in the Reference state to about 20%, mostly of introduced species. Few to no seedlings and saplings of native tree and shrub species occur in this phase.

State 3 Invaded Overstory and Understory State

This state contains one community phase. The vegetation consists almost entirely of introduced species. Restoration to State 1 Reference would be very difficult.

Community 3.1 Strawberry guava/Kahila garland-lily (kahili ginger)/sphagnum

Figure 15. Melaleuca overstory with kahili ginger understory. D Clausnitzer generic photo

Figure 16. Closeup of ginger root system on soil surface. 9/11/08 D Clausnitzer generic photo

Figure 17. Hilograss dominating soil surface. 4/27/07 D Clausnitzer MU426

This community phase may have a few remnant native trees and tree ferns. Introduced species dominate all strata.

Forest overstory. A few ohia lehua (*Metrosideros polymorpha*) remain in the overstory. Some scattered strawberry guava (*Psidium cattleianum*) have grown into the overstory. Other introduced tree species such as paperbark (*Melaleuca quinquinervia*) sometimes occur in the overstory.

Forest understory. Kahili ginger or Kahila garland-lily (*Hedychium gardnerianum*) is typically the dominant species, forming a dense, uniform cover about five feet (1.5 meters) tall. Strawberry guava appears able to reproduce and emerge through the ginger stands to some extent. A few hapuu (*Cibotium glaucum*) remain above the ginger stands but do not reproduce. Introduced grasses and a few introduced forbs are able to reproduce and grow in gaps within the understory.

Transition T1A

State 1 to 2

This state transitions to State 2 Invaded Understory by gradual replacement of the understory by introduced plant species that outcompete native understory species. This process is accelerated by ungulate foraging that disturbs the soil surface and directly destroys native plants and prevents their regeneration.

Restoration pathway R2A

State 2 to 1

It may be possible to restore this state to State 1 Reference. Before restoration of native plants, introduced understory plants must be eliminated by herbicide, and ungulates must be excluded from the restoration site.

Transition T2A

State 2 to 3

This state will transition to State 3 Invaded Overstory and Understory. Native species are unable to successfully regenerate due to the dense, shady weed understory. Mature native plants eventually die out and are replaced by

more competitive, introduced species.

Animal community

Native forest birds have been observed in the Reference community phase. Elepaio (*Chasiempis sandwichensis*), Amakihi (*Hemignathus virens*), Apapane (*Himatione sanguinea*), and liwi (*Vestiaria coccinea*) occur. Also present is the Hawaiian Hawk or Io (*Buteo solitarius*) (Maly and Maly 2004). Newell Shearwater, or Ao (*Puffinus newelli*) are seabirds that have been observed.

Non-native forest birds include Hwamei (*Garrulax canorus*), Japanese White-eye (*Zosterops japonicus*), and Northern Cardinal (*Cardinalis cardinalis*).

Feral pigs and cattle are abundant and are very destructive to native vegetation.

Hydrological functions

Small variations in elevation and slope produce visible variations in the vegetation and soil surface cover within this ecological site. Slightly higher, better drained locations typically have taller vegetation and less, or thinner, cover of sphagnum on the soil.

Recreational uses

Most of this ecological site is inaccessible to the public. Where access is possible, hunting and hiking may be conducted.

Wood products

None.

Other products

None.

Other information

Definitions

These definitions have been greatly simplified for brevity and do not cover every aspect of each topic.

Aa lava: A type of basaltic lava having a rough, jagged, clinkery surface and a vesicular interior.

Alluvial: Materials or processes associated with transportation and/or deposition by running water.

Aquic soil moisture regime: A regime in which the soil is free of dissolved oxygen because it is saturated by water. This regime typically exists in bogs or swamps.

Aridic soil moisture regime: A regime in which defined parts of the soil are, in normal years, dry for more than half of the growing season and moist for less than 90 consecutive days during the growing season. In Hawaii it is associated with hot, dry areas with plants such as kiawe, wiliwili, and buffelgrass. The terms aridic and torric are basically the same.

Ash field: a land area covered by a thick or distinctive deposit of volcanic ash that can be traced to a specific source and has well defined boundaries. The term "ash flow" is erroneously used in the Physiographic section of this ESD due to a flaw in the national database.

Ashy: A "soil texture modifier" for volcanic ash soils having a water content at the crop wilting point of less than 30 percent; a soil that holds relatively less water than "medial" and "hydrous" soils.

Available water capacity: The amount of soil water available to plants to the depth of the first root-restricting layer.

Basal area or basal cover: The cross sectional area of the stem or stems of a plant or of all plants in a stand.

Blue rock: The dense, hard, massive lava that forms the inner core of an aa lava flow.

Bulk density: the weight of dry soil per unit of volume. Lower bulk density indicates a greater amount of pore space that can hold water and air in a soil.

CaCO₃ equivalent: The amount of free lime in a soil. Free lime exists as solid material and typically occurs in regions with a dry climate.

Canopy cover: The percentage of ground covered by the vertical projection downward of the outermost perimeter of the spread of plant foliage. Small openings within the canopy are included.

Community pathway: A description of the causes of shifts between community phases. A community pathway is reversible and is attributable to succession, natural disturbances, short-term climatic variation, and facilitating practices, such as grazing management.

Community phase: A unique assemblage of plants and associated dynamic soil properties within a state.

Dominant species: Plant species or species groups that exert considerable influence upon a community due to size, abundance, or cover.

Drainage class: The frequency and duration of a water table in a soil. There are seven drainage classes, ranging from “excessively drained” (soils with very rare or very deep water tables) to “well drained” (soils that provide ample water for plant growth but are not so wet as to inhibit root growth) to “very poorly drained” (soils with a water table at or near the surface during much of the growing season that inhibits growth of most plants).

Electrical conductivity (EC): A measure of the salinity of a soil. The standard unit is deciSiemens per meter (dS/m), which is numerically equivalent to millimhos per centimeter (mmhos/cm). An EC greater than about 4 dS/m indicates a salinity level that is unfavorable to growth of most plants.

Friability: A soil consistency term pertaining to the ease of crumbling of soils.

Hydrous: A “soil texture modifier” for volcanic ash soils having a water content at the crop wilting point of 100 percent or more; a soil that holds more water than “medial” or “ashy” soils.

Ion exchange capacity: The ability of soil materials such as clay or organic matter to retain ions (which may be plant nutrients) and to release those ions for uptake by roots.

Isohyperthermic soil temperature regime: A regime in which mean annual soil temperature is 72 degrees F (22 degrees C) or higher and mean summer and mean winter soil temperatures differ by less than 11 degrees F (6 degrees C) at a specified depth.

Isomesic soil temperature regime: A regime in which mean annual soil temperature is 47 degrees F (8 degrees C) or higher but lower than 59 degrees F (15 degrees C) and mean summer and mean winter soil temperatures differ by less than 11 degrees F (6 degrees C) at a specified depth.

Isothermic soil temperature regime: A regime in which mean annual soil temperature is 59 degrees F (15 degrees C) or higher but lower than 72 degrees F (22 degrees C) and mean summer and mean winter soil temperatures differ by less than 11 degrees F (6 degrees C) at a specified depth.

Kipuka: An area of land surrounded by younger (more recent) lava. Soils and plant communities within a kipuka are older than, and often quite different from, those on the surrounding surfaces.

Major Land Resource Area (MLRA): A geographic area defined by NRCS that is characterized by a particular pattern of soils, climate, water resources, and land uses. The island of Hawaii contains nine MLRAs, some of which also occur on other islands in the state.

Makai: a Hawaiian word meaning “toward the sea.”

Mauka: a Hawaiian word meaning “toward the mountain” or “inland.”

Medial: A “soil texture modifier” for volcanic ash soils having a water content at the crop wilting point of 30 to 100 percent; a soil that holds an amount of water intermediate to “hydrous” or “ashy” soils.

Naturalized plant community: A community dominated by adapted, introduced species. It is a relatively stable community resulting from secondary succession after disturbance. Most grasslands in Hawaii are in this category.

Pahoehoe lava: A type of basaltic lava with a smooth, billowy, or rope-like surface and vesicular interior.

Parent material: Unconsolidated and chemically weathered material from which a soil is developed.

Perudic soil moisture regime: A very wet regime found where precipitation exceeds evapotranspiration in all months of normal years. On the island of Hawaii, this regime is found on top of Kohala and on parts of the windward side of Mauna Kea.

pH: The numerical expression of the relative acidity or alkalinity of a soil sample. A pH of 7 is neutral; a pH below 7 is acidic and a pH above 7 is basic.

Phosphorus adsorption: The ability of soil materials to tightly retain phosphorous ions, which are a plant nutrient. Some volcanic ash soils retain phosphorus so strongly that it is partly unavailable to plants.

Reference community phase: The phase exhibiting the characteristics of the reference state and containing the full complement of plant species that historically occupied the site. It is the community phase used to classify an ecological site.

Reference state: A state that describes the ecological potential and natural or historical range of variability of an ecological site.

Restoration pathway: A term describing the environmental conditions and practices that are required to recover a state that has undergone a transition.

Sodium adsorption ratio (SAR): A measure of the amount of dissolved sodium relative to calcium and magnesium in the soil water. SAR values higher than 13 create soil conditions unfavorable to most plants.

Soil moisture regime: A term referring to the presence or absence either of ground water or of water held at a tension of less than 1500 kPa (the crop wilting point) in the soil or in specific horizons during periods of the year.

Soil temperature regime: A defined class based on mean annual soil temperature and on differences between summer and winter temperatures at a specified depth.

Soil reaction: Numerical expression in pH units of the relative acidity or alkalinity of a soil.

State: One or more community phases and their soil properties that interact with the abiotic and biotic environment to produce persistent functional and structural attributes associated with a characteristic range of variability.

State-and-transition model: A method used to display information about relationships between vegetation, soil, animals, hydrology, disturbances, and management actions on an ecological site.

Torric soil moisture regime: See Aridic soil moisture regime.

Transition: A term describing the biotic or abiotic variables or events that contribute to loss of state resilience and result in shifts between states.

Udic soil moisture regime: A regime in which the soil is not dry in any part for as long as 90 cumulative days in normal years, and so provides ample moisture for plants. In Hawaii it is associated with forests in which hapuu (tree ferns) are usually moderately to highly abundant.

Ustic soil moisture regime: A regime in which moisture is limited but present at a time when conditions are suitable for plant growth. In Hawaii it usually is associated with dry forests and subalpine shrublands.

Type locality

Location 1: Hawaii County, HI	
Latitude	20° 4' 4"
Longitude	155° 40' 14"

General legal description	In Kohala State Forest Reserve, up Reservoir Road above Waimea. Drive almost to end of road at head of Waipio Valley. Walk W and then S for 200 yards along cleared foot trail.

Rangeland health reference sheet

Interpreting Indicators of Rangeland Health is a qualitative assessment protocol used to determine ecosystem condition based on benchmark characteristics described in the Reference Sheet. A suite of 17 (or more) indicators are typically considered in an assessment. The ecological site(s) representative of an assessment location must be known prior to applying the protocol and must be verified based on soils and climate. Current plant community cannot be used to identify the ecological site.

Composition (Indicators 10 and 12) based on	Annual Production

Indicators

1. **Number and extent of rills:**

2. **Presence of water flow patterns:**

3. **Number and height of erosional pedestals or terracettes:**

4. **Bare ground from Ecological Site Description or other studies (rock, litter, lichen, moss, plant canopy are not bare ground):**

5. **Number of gullies and erosion associated with gullies:**

6. **Extent of wind scoured, blowouts and/or depositional areas:**

7. **Amount of litter movement (describe size and distance expected to travel):**

8. **Soil surface (top few mm) resistance to erosion (stability values are averages - most sites will show a range of values):**

9. **Soil surface structure and SOM content (include type of structure and A-horizon color and thickness):**

10. **Effect of community phase composition (relative proportion of different functional groups) and spatial distribution on infiltration and runoff:**

11. **Presence and thickness of compaction layer (usually none; describe soil profile features which may be mistaken for compaction on this site):**

12. **Functional/Structural Groups (list in order of descending dominance by above-ground annual-production or live foliar cover using symbols: >>, >, = to indicate much greater than, greater than, and equal to):**

Dominant:

Sub-dominant:

Other:

Additional:

13. **Amount of plant mortality and decadence (include which functional groups are expected to show mortality or decadence):**

14. **Average percent litter cover (%) and depth (in):**

15. **Expected annual annual-production (this is TOTAL above-ground annual-production, not just forage annual-production):**

16. **Potential invasive (including noxious) species (native and non-native). List species which BOTH characterize degraded states and have the potential to become a dominant or co-dominant species on the ecological site if their future establishment and growth is not actively controlled by management interventions. Species that become dominant for only one to several years (e.g., short-term response to drought or wildfire) are not invasive plants. Note that unlike other indicators, we are describing what is NOT expected in the reference state for the ecological site:**

17. **Perennial plant reproductive capability:**
